ABSTRACT

A model-independent reconstruction of mechanical profiles (density, pressure) of the solar interior is outlined using the adiabatic sound speed and bouyancy frequency profiles. These can be inferred from helioseismology if both p - and g -mode frequencies are measured. A simulated reconstruction is presented using a solar model bouyancy frequency and available sound speed data.

Subject headings: Sun: interior — Sun: oscillations

To appear in **the Astrophysical Journal**: 10 September 2000

Standard solar models (SSMs) are now very accurate, exemplified by the work of Bahcall et al. (Bahcall et al. 1998; Pinsonneault 1998) and Turck-Chièze et al. (Brun et al. 1998). But confidence in predicted solar neutrino fluxes is enhanced by checks of the solar core depending on only a few general assumptions, independent of detailed models. This can be done with helioseismology, although the g -modes are needed. Serious claims of g -modes observations have been put forward (Hill & Gu 1990; Thomson et al. 1995) but remain controversial (Guenther & Sills 1995; Lou 1996). Nonetheless, the g -modes will undoubtedly be observed at some point, despite their attenuation by the convective zone.

We assume negligible radiation pressure $P_\gamma \ll P_{\text{gas}}$ and no significant departures from an ideal gas ($P = P_{\text{gas}} = \rho \mathcal{R}T/\mu$).

$$\begin{aligned} \Gamma &= d \ln P / d \ln \rho \quad , \quad \Gamma_{\text{ad}} = (\partial \ln P / \partial \rho)_{\text{ad}} \quad , \\ \nabla &= d \ln T / d \ln P \quad , \quad \nabla_{\text{ad}} = (\partial \ln T / \partial \ln P)_{\text{ad}} \quad . \end{aligned} \tag{1}$$

¹Contribution to the INT Low-Energy Neutrino Physics Workshop, Univ. Washington, Seattle (June-September 1999).

$\Gamma_{\text{ad}} = 5/3$, $\nabla_{\text{ad}} = 2/5$ for a monatomic gas. The Brunt-Väisälä (bouyancy) frequency $N(r)$:

$$N^2 = \frac{g}{\lambda_P} \cdot \left[\frac{1}{\Gamma} - \frac{1}{\Gamma_{\text{ad}}} \right] = (\rho g^2 / P) \cdot [\nabla_{\text{ad}} - \nabla + \nabla_{\mu}] \quad , \quad \lambda_P^{-1} = -d \ln P / dr \quad , \quad (2)$$

with $\nabla_{\mu} = d \ln \mu / d \ln P$, is real for propagating g -waves, outside any convective zones. The base of the solar convective zone $r_{\text{BCZ}} = (0.709)R_{\odot}$ (Gough et al. 1996). The adiabatic squared sound speed $c_{\text{ad}}^2 = \Gamma_{\text{ad}} \cdot P / \rho$.

The adiabatic seismology formalism here follows Unno et al. (1989), with some differences in notation. The seismic modes are labeled by radial index n (number of radial nodes) and angular indices l and m ; frequencies degenerate in the last if rotation is ignored. The spectrum exhibits “middle” f (fundamental or $n = 0$, $l > 1$) modes and the p - (g -) modes rising above (falling below) the f mode in ν for $n > 0$, $l > 0$. For large n , the p - and g -modes are concentrated near the surface and the center, respectively. Their frequencies ν_p and ν_g are

$$\nu_p^{-1}(n, l) \simeq \frac{2}{n + \frac{1}{2}\sqrt{l(l+1)}} \int_0^{R_{\odot}} \frac{dr}{c_{\text{ad}}(r)} \quad , \quad \nu_g(n, l) \simeq \frac{\sqrt{l(l+1)}}{2n\pi^2} \int_0^{r_{\text{BCZ}}} \frac{dr}{r} N(r) \quad , \quad (3)$$

for large n . (l cannot be large in ν_p .) A large set of measured frequencies allow reconstruction of the $c_{\text{ad}}(r)$ and $N(r)$ profiles. The Bahcall-Pinsonneault 1998 (BP98) SSM is used here when specific numerical results are needed.

1. Tests of Hydrostatic Equilibrium

Present helioseismic data rule out the $\Gamma = 5/3$ convective polytrope deep into the core (Basu et al. 1997; Christensen-Dalsgaard 1997). Hydrostatic equilibrium is tested by correct prediction of the $\nu_g(n, l)$, $n \gg 1$. Success here would limit any remaining possibility of convection at the center (otherwise $N^2 < 0$), although the Sun is not far from this state ($M \simeq 1.1M_{\odot}$ in standard calculations; see Kippenhahn & Weigert 1990). An equivalent test of hydrostatic equilibrium at the center is provided by the sound speed slope, measurable in principle with p -modes alone:

$$\frac{dc_{\text{ad}}^2}{dr} = -g\Gamma_{\text{ad}} \cdot \left(1 - \frac{1}{\Gamma} \right) + \frac{P}{\rho} \cdot \frac{d\Gamma_{\text{ad}}}{dr} \quad , \quad 1 - \frac{1}{\Gamma} = \nabla - \nabla_{\mu} \quad . \quad (4)$$

Assume $d\Gamma_{\text{ad}}/dr = 0$ in the core and a non-singular mass distribution, so that

$$g = Gm/r^2 = (4\pi G/3)\rho_c r \rightarrow 0 \text{ as } r \rightarrow 0 \quad . \quad (5)$$

Thus $dc_{\text{ad}}^2(0)/dr$ must vanish.

The measured sound speed slope places a limit on an unperturbed state with non-zero velocity field $\mathbf{v}_0$, taken here as radial for simplicity. This test checks for the presence of convective motion that does not efficiently transfer heat. Such convection would not directly affect Γ and the P/ρ profile and thus is not ruled out in general by current p -mode helioseismic data. Hydrostatic equilibrium is modified to

$$-\frac{dP}{dr} = \rho g + \rho v_0 \frac{dv_0}{dr} \quad , \quad (6)$$

ignoring spherical-symmetry-breaking rotation and magnetic effects, also calculable. Assume again $d\Gamma_{\text{ad}}/dr = 0$ in the core and $g(0) = 0$. Equation (4) no longer vanishes at the center and instead yields

$$\frac{dc_{\text{ad}}^2(0)}{dr} = -\Gamma_{\text{ad}} \cdot v_0(0) \frac{dv_0(0)}{dr} \cdot \left[1 - \frac{1}{\Gamma(0)}\right] \quad .$$

Equivalently, in terms of g -modes, $\nu_g(n, l)$ is corrected (to linear order in v_0) by the “expectation value” in the (n, l) mode of $k_r v_0/2\pi$, where k_r = radial wavenumber. The related length scale $\approx R_\odot/\text{few}$ for low- n modes; but for high- n g -modes concentrated near the center, it is the central scale $R_0 : R_0^2 = 3P_c/2\pi G\rho_c^2$, with $R_0/R_\odot = 0.12$ for the present SSM (Kennedy & Bludman 1999). For large n ,

$$k_r \rightarrow \frac{n}{R_0 \Omega_g} \cdot \sqrt{\frac{8\pi^3 \rho_c G}{3} \left[\frac{1}{\Gamma(0)} - \frac{1}{\Gamma_{\text{ad}}} \right]} \quad , \quad \Omega_g = \int_0^{r_{\text{BCZ}}} \frac{dr}{r} N(r) \quad . \quad (7)$$

A conservative relative observational error for ν_g is 0.003, while the relative theoretical uncertainty $\simeq 0.001$ (Hill & Gu 1990; Guenther & Sills 1995; Bahcall et al. 1998). Thus a direct bound on the core $v_0 \lesssim 2\pi\nu_g(n, l)/k_r \sim (7.5 \times 10^7 \text{ cm sec}^{-1}) \sqrt{l(l+1)}/n^2$, or $1.2 \times 10^5 \text{ cm sec}^{-1}$ for $l = 1, n = 30$, is feasible, independent of azimuthal splitting by m .

2. Mechanical Profiles

The $N(r)$ and $c_{\text{ad}}(r)$ profiles are sufficient to reconstruct uniquely the mechanical (hydrostatic) profiles. $N(r)$ and $dc_{\text{ad}}(r)/dr$ are proportional, either one controlling the $\nu_g(n, l)$:

$$\frac{dc_{\text{ad}}(r)}{dr} = -\frac{N(r)/2}{\sqrt{\Gamma_{\text{ad}}/\Gamma(r) - 1}} \cdot \left[1 - \frac{1}{\Gamma(r)}\right] \Gamma_{\text{ad}} \quad . \quad (8)$$

Gravity modes are a result of the inhomogeneity of $c_{\text{ad}}(r)$. Assuming $d\Gamma_{\text{ad}}/dr = 0$, Γ satisfies a quadratic equation,

$$(1 + \mathcal{D})\Gamma^2 - (2 + \mathcal{D} \cdot \Gamma_{\text{ad}})\Gamma + 1 = 0 \quad , \quad \mathcal{D}(r) \equiv \left[\frac{2 \cdot dc_{\text{ad}}(r)/dr}{\Gamma_{\text{ad}} \cdot N(r)} \right]^2 \quad , \quad (9)$$

with one physical root,

$$\Gamma(r) = \frac{2 + \mathcal{D}(r) \cdot \Gamma_{\text{ad}} + \sqrt{[2 + \mathcal{D}(r) \cdot \Gamma_{\text{ad}}]^2 - 4[1 + \mathcal{D}(r)]}}{2[1 + \mathcal{D}(r)]} . \quad (10)$$

Thus the $\Gamma(r)$ profile is reconstructible with $N(r)$ and a numerical derivative of $c_{\text{ad}}(r)$. Note that $\Gamma = 1$ when dc_{ad}/dr and $\mathcal{D} = 0$.

The mass and pressure profiles then follow:

$$\begin{aligned} Gm(r) &= -\frac{r^2 \cdot dc_{\text{ad}}^2(r)/dr}{\Gamma_{\text{ad}} \cdot [1 - 1/\Gamma(r)]} , \\ 4\pi G\rho_c &= -\frac{6 \cdot dc_{\text{ad}}^2(0)/dr^2}{\Gamma_{\text{ad}} \cdot [1 - 1/\Gamma(0)]} , \\ P(r) &= \frac{\rho(r) \cdot c_{\text{ad}}^2(r)}{\Gamma_{\text{ad}}} , \end{aligned} \quad (11)$$

where $\rho(r)$ is obtained from $m(r)$. Note that $m > 0$, because $\Gamma > 1$ if $dc_{\text{ad}}^2/dr < 0$ and $\Gamma < 1$ if $dc_{\text{ad}}^2/dr > 0$. (The $dc_{\text{ad}}^2/dr = 0$ and $r \rightarrow 0$ limits are well-defined in the ratios.) The present SSM inner core is an example of the $\Gamma < 1$ case. Dimensionless structure in terms of homology variables can also be derived (Kennedy & Bludman 1999).

Direct methods of inversion without a reference SSM, based on p -modes alone and including use of the sound speed slope as a diagnostic of the equation of state, are discussed in the older literature (Gough 1984; Christensen-Dalsgaard et al. 1985; Gough & Toomre 1991; Gough et al. 1995) and, since the advent of SOHO, GONG, and BiSON/LOWL, by Gough et al. (1996), Basu et al. (1997), and Christensen-Dalsgaard (1997). Since the ν , especially at long wavelength, are affected by the whole Sun, errors in the inferred spatial structure are strongly correlated. An inversion for $N(r)$, like the inversion for $c_{\text{ad}}(r)$, will have uncertainties in both N and the position r . The derived profiles (11) will have errors compounded from all these sources: $c_{\text{ad}}(r)$, $N(r)$, and r , and thus larger than errors in any one.

3. Numerical Test of the Method

As the SSM evolves, ∇ falls while ∇_μ increases from zero, the core becoming more concentrated. Helioseismology is adiabatic and non-evolutionary and cannot give the thermal or chemical structure without further assumptions or a full SSM. Many SSM core features can be understood via mechanical-thermal core homology without a detailed model (Bludman & Kennedy 1996). Homology applied to the *core only* is valid for power-law opacity

and luminosity generation and does *not* require a polytrope. A polytrope is not even approximately valid for the present SSM core in any case (Kennedy & Bludman 1999). The homology in reality is violated somewhat, as the exponents are not constant and the luminosity is not exclusively produced by one reaction chain.² But an accurate thermal and chemical reconstruction is not much less complicated and requires no fewer assumptions than a full SSM. On the other hand, the mechanical structure of a SSM can be specified by the model-independent reconstruction of Section 2, rather than calculated.

As ρ and P are in principle inferable from helioseismology, the numerical precision of the reconstruction can be estimated. No g -mode measurements are now available, so the SSM bouyancy frequency is used here. Combining $c_{\text{ad}}(r)$, $dc_{\text{ad}}(r)/dr$, and the SSM $N(r)$ and assuming $\Gamma_{\text{ad}} = 5/3$, the profile $\mathcal{D}(r)$ is obtained (9) and hence $\Gamma(r)$.

Figure 1 shows the measured sound speed below the convection zone, the points being fixed by helioseismic inversion (Christensen-Dalsgaard 1997). The BP98 SSM Γ and N profiles, respectively, are shown in Figs. 2(a,b). In Figure 3 is displayed the ratio of the reconstructed to the SSM $\Gamma(r)$. The helioseismic inversion points are separated by steps of $\Delta(r/R_{\odot}) \simeq 0.01$, and we should thus expect agreement with the SSM at level of about one percent, consistent with Fig. 3. The inner boundary at $r/R_{\odot} = 0.05$ marks the terminus of the present helioseismic inversion, the outer boundary the base of the convective zone at $r_{\text{BCZ}}/R_{\odot} = 0.71$. Cutting off the fit at both ends introduces artificial errors, and thus the first three and last three points are not shown in Fig. 3.

The agreement of a true reconstruction with the SSM should be better than Fig. 3, but the overall uncertainty would be somewhat larger than a percent, reflecting the $c_{\text{ad}}(r)$ uncertainty; the additional uncertainties due to a measured, rather than a model, $N(r)$ profile; and the errors induced by spatial correlation of the helioseismic inversion mesh points.

4. Summary

Some solar core tests are proposed, independent of model details. Measured p - and g -modes are needed to reconstruct $c_{\text{ad}}^2(r)$ and $N^2(r)$ uniquely and independently of a reference SSM, with only general physical assumptions: hydrostatic equilibrium, the ideal gas law, and known, constant Γ_{ad} .

²If the specific luminosity production is $\varepsilon = \varepsilon_o \rho^{\lambda} T^{\theta}$ and the specific opacity is $\kappa = \kappa_o \rho^q T^{-s}$, the homology yields $r^{\theta-s+3\lambda+3q} \sim \varepsilon_o \kappa_o \cdot \mu^{\theta-s-4} \cdot m^{\theta-s+\lambda+q-2}$ (correcting an error in Bludman & Kennedy 1996).

Absence of core convection implies $N^2 > 0$ in (2) and the existence of $\nu_g(n, l)$ for high n (3). A non-singular, static mass distribution implies vanishing of the sound speed slope (4) at the center (5). The measured slope and/or high- n ν_g can set a limit $\sim \mathcal{O}(10^5)$ cm sec⁻¹ on a central velocity field. Reconstruction of the solar interior mechanical structure follows (10-11) from $c_{\text{ad}}(r)$, $dc_{\text{ad}}(r)/dr$, and $N(r)$. A test of the method is presented, using the available, measured $c_{\text{ad}}(r)$ and a model $N(r)$ profile.³

The c_{ad} and N profiles to the origin are essential for testing the SSM in the inner core, the critical region for the solar neutrino problem, where the higher-energy Be and B neutrinos are produced and where solar structure becomes strongly non-polytropic (Bahcall 1988; Kennedy & Bludman 1999). p -mode data on a finer radial mesh and extending to the center are presently lacking, but might become available soon, even if g -mode measurements remain elusive.

Truly independent tests of thermal structure and chemical evolution would require comparison with other Sun-like stars, in particular via asteroseismology (Deubner et al. 1998). With the appropriate changes, the method outlined here can be used to analyze such stars as well.

The author thanks John Bahcall (Institute for Advanced Study) and Marc Pinsonneault of (Ohio State Univ.) for the BP98 model tables and Jørgen Christensen-Dalsgaard (Aarhus Univ.) for helioseismic data.⁴ This work is partly based on research done in collaboration with Sidney Bludman (Univ. Pennsylvania and DESY) and was supported by the Department of Energy under Grant Nos. DE-FG06-90ER40561 at the Institute for Nuclear Theory (Univ. Washington) and DE-FG02-97ER41029 at the Institute for Fundamental Theory (Univ. Florida), and by the Eppley Foundation for Research. The author is also grateful to the Aspen Center for Physics for its hospitality.
